

Procedures - Correction of Asymmetry

Breast Asymmetry is a condition where one breast is larger than the other. The right versus the left breast of any woman is very often of different size and even a different shape. Although common, these differences are perceptible but not very great. There are options on how to correct this condition.

Surgery for breast asymmetry may involve augmentation of one or both breasts, or reduction mammoplasty of one or both breasts.

Breast augmentation can be performed on one breast, increasing its size and making it similar to the other one. Breast reduction can also be performed to reduce the larger of the two breasts. This involves removal of excess fat and skin. Either procedure results in breasts that are more similar in size.

Correcting breast asymmetry has not only helped women improve upon their appearance, but it can also provide a boost to their self-esteem and self-confidence. The choice of which procedure to undergo to correct breast asymmetry is something Pure Aesthetics will discuss with you. We will discuss these options in more detail with you during your initial consultation.
